

A current 2nd master's student of Computer Science student at Stevens Institute of Technology (Graduated from Stevens in Software Engineering), I have a unique blend of experience in that I have a fine-arts base coupled with twenty years of practical experience in user research, information architecture and software functional design, and an understanding of the frontline of how poorly designed information flows are a cause of human-experience hotspots and technical gaps in complex socio-technical systems. I am now committed to the next-gen AI-powered HCI field, respectively:

1. RafFlow - For the Singapore Raffles Design Institute Shanghai Campus, being a student-lecturer coursework instruction, submission, and grading information system retrieved from the former ERP systems educational section and repurposed to a solid, simple to use, and AI-enhanced system. I have done research and forged 300+ art and design students at Raffles Shanghai on my own (2023-2025). It decreased the faculty work-time by 60 per cent and increased teaching advice and grading effectiveness rates by two-fold.
2. DouFunDriving-HMI - a real-time primary-secondary co-driving HMI developed in collaboration with Prof. Feng Lin (Donghua Visual Communication AGI Lab). Under consideration by the Donghua University AGI Research Hub, the English version is finished and is intended to be submitted to the International Journal of Human-Computer Studies (IJHCS, Elsevier, IF 5.1), one of the HCI journals that Donghua University has collaborated with in the past, in early 2026.
3. RAIDScript - an experimental domain-specific language in the niche space of AI-augmented Programming Script Language, I researched and designed during my studies at Stevens, that allows zero-code multimodal co-creation in the next generation of information applications developers who have just a limited coding capacity with a sub-par computer expertise background.

Working as a veteran, since 2000, I have witnessed several cases when the poorly-designed information flows have locked non-technical partners out of the system, in the case of 51job, Zhaopin, and China UnionPay, which currently serve more than 100 million users. This direct experience of user research, information architecture, and software functional design directly informed my research today. I see strong alignment with Prof. Mor Naaman's research on human-AI collaboration and Prof. Wendy Ju's work on automotive HMI, both directly connected to my AI-augmented learning and co-driving systems.

My PhD goal is to establish myself in the highly desirable centers and laboratories of Cornell, collaborate with my brilliant colleagues and global professors in highly transformative and innovative research, and realize my research objectives. Having two master's of Stevens (2023, 3.73 GPA, Software Engineering; 2026, Computer Science), and experience in production-scale deployments, I can provide instant contribution to the human-centered AI ecosystem at Cornell Tech - by bringing to New York, the creative hub of the city, the capability to revolutionize its processes, accelerate the prototype to impact cycle.
